Introduction

Our group of research (Applied Computational Chemistry and Molecular Modeling Group) is studying different industrial processes by means of Molecular Dynamics:

CO₂ capture in post-combustion flows

How to increase the CO₂ capture/sequestration by adsorbent materials?

how molecular dynamics simulations have helped in the processes behind the two former topics

Faculty of Chemistry and Pharmacy – University of Sofia – Sofia, Bulgaria, December 4th-5th 2017

Introduction

Our group of research (Applied Computational Chemistry and Molecular Modeling Group) is studying different industrial processes by means of Molecular Dynamics:

Sensible thermal storage

How to increase the C_p in molten salts (solar salts) for using in solar plants?

how molecular dynamics simulations have helped in the processes behind the two former topics

Faculty of Chemistry and Pharmacy – University of Sofia – Sofia, Bulgaria, December 4th-5th 2017

Introduction

Our group of research (Applied Computational Chemistry and Molecular Modeling Group) is studying different industrial processes by means of Molecular Dynamics:

Enhanced Oil Recovery Techniques

How to increase the amount of oil recovered in third stage technologies?

how molecular dynamics simulations have helped in the processes behind the two former topics

Faculty of Chemistry and Pharmacy – University of Sofia – Sofia, Bulgaria, December 4th-5th 2017

CO₂ capture in post-combustion flows

Carbon Emission Problem

After a decade of very high annual growth rates of global CO₂ emissions of 4% on average, the growth in emissions almost stalled in 2014 with an increase of only 0.5% to 35.7 billion tonnes CO₂. Power plants are responsible for about 40% of the total.

It is a “good new” but it is necessary to keep on decreasing carbon emissions

Faculty of Chemistry and Pharmacy – University of Sofia – Sofia, Bulgaria, December 4th-5th 2017

CO₂ capture in post-combustion flows

Technologies for CO₂ capture

What is done in industry nowadays?

Faculty of Chemistry and Pharmacy – University of Sofia – Sofia, Bulgaria, December 4th-5th 2017

Technologies for CO₂ capture

What is done in industry nowadays?

Separation with Sorbents (adsorption)

Post-combustion CO₂ capture

(Flue gas composition: 14–16%)

Pressure Swing Adsorption (PSA):

- 1st, the flue gas mixture enters into bed 1 (at 1 bar).
- 2nd, the mixture pressurizes bed 1 in the range (7–30 bars).
at this conditions CO₂ adsorbs and the other components not, exiting from the top of the bed.
- 3rd, the first bed is depressurized to atmospheric pressure.
at this conditions the CO₂ is removed and driven to a receiver tank and the adsorbent material is regenerated.
At the same time the cycle is repeated in bed 2.

Faculty of Chemistry and Pharmacy – University of Sofia – Sofia, Bulgaria, December 4th-5th 2017

Technologies for CO₂ capture

What is done in industry nowadays?

Separation with Sorbents (adsorption)

Other Swing Adsorption-Desorption processes:

VSA: Vacuum Swing Adsorption

Materials for CO₂ capture

How the materials for CO₂ capture should be?

- High CO₂ working capacities
- High selectivity towards CO₂
- Suitable for a wide range of temperatures and pressures
- No degradable in presence of impurities
- Easy to regenerate
- Small increase in the price of electricity

Metal-organic frameworks (MOFs)
e.g. CuBTC

Zeolites
porous aluminosilicate materials

Faujasite 13X Na₈₈[Si₁₀₄Al₁₈₈O₃₈₄]

Porous Material of Si/Al ratio 1.2 (88-FAU)

is the one used today in industrial processes

Na:gray / Al:pink / Si:yellow / O:red

Materials for CO₂ capture

Supercages
pore size (>8 Å)

CO₂ capture in post-combustion flows

How do we simulate the capture process by adsorbents?

It corresponds to a mechanical system of particles in thermodynamic equilibrium (thermal and chemical) with a reservoir of gas (i.e., the system can exchange energy and particles with the reservoir).

The interaction of particles is described by validated force fields and these particles are inserted, moved or eliminated from the system in order to achieve the equilibrium state when chemical potentials of reservoir and system become equal at a fixed P and T of the reservoir.

CO₂ capture in post-combustion flows

How do we simulate the capture process by adsorbents?

Faculty of Chemistry and Pharmacy – University of Sofia – Sofia, Bulgaria, December 4th-5th 2017

CO₂ capture in post-combustion flows

Adsorption Material: Faujasite (FAU)

for every Si atom substituted by Al one Na⁺ atom is also introduced to cancel the negative charge

Possible structures

- from totally silicified (silicalite, 0-FAU)
- to 96-FAU, maximum number of Al per unit cell (according to Lowenstein's rules)

Faculty of Chemistry and Pharmacy – University of Sofia – Sofia, Bulgaria, December 4th-5th 2017

CO₂ capture in post-combustion flows

Mixture results

15% CO₂ / 80% N₂ / 5% O₂ (T = 313 K)

- The effectiveness for CO₂ capture and separation in FAU structures is highly dependent on the Al content but also on the process conditions (feeding and regeneration pressure).
- FAU with high Al or Na⁺ content would adsorb more CO₂ molecules under adsorption conditions (i.e., high pressure), but at the desorption step (i.e., low pressure) the number of desorbed molecules will be lower, due to the high isosteric heat of adsorption.
- Selectivity is not enough, for a given operative conditions it is necessary to select the most suitable FAU.

Optimal Faujaite structures for post combustion CO₂ capture and separation in different swing adsorption processes
H. Prats, D. Bahamón, G. Alonso, X. Giménez, P. Gamallo, R. Sayós, J. CO₂ UHI 19(2017) 100-111 & 21 (2017) 261-269.

CO₂ capture in post-combustion flows

Adsorbent evaluation criteria

- Working capacity is the amount of CO₂ that can be expected to be captured by a specified amount of adsorbent during one adsorption-desorption cycle.

- There is no best structure. Instead, depending on the process and the operating conditions (i.e., T_{ads}, T_{des}, P_{ads}, P_{des}) one or another structure should be chosen in order to maximize the WC.

Optimal Faujaite structures for post combustion CO₂ capture and separation in different swing adsorption processes

Thermal Storage

Energy Storage systems are the key point for the introduction of renewable energies in the current energetic system.

BRVA, Innotrium, Loream Energy

Types of storage:

- Mecanic
- Electrochemical
- Thermal (sensible, latent, chemical)
- Chemical
- Electromagnetic

Why molten salts?

Requirements for a Material for Sensible Thermal Storage:

- High density
- High temperature of stability
- High energetic density
- High thermal conductivity
- Low thermal diffusivity
- High heat or thermal capacity

Contrarily to conventional thermal storage materials (i.e., paraffin, oils,...) molten salts present thermal stability at high temperatures.

BUT NO MODEL IS VALIDATED FOR EXPLAINING THE ANOMALOUS EFFECT OF INCREASING THE THERMAL CAPACITY OF SOLAR SALTS.

Moderate C_p values

In the last years:

NANOFLUIDS → Introduction of nanoparticles in molten salts systems

Increasing C_p between 10-50% at low concentrations of nanoparticles.

Concentrate Solar Power Stations

from General Electric

The fluids used as thermal storage in Solar Power Stations are molten salts. Concretely, "solar salts":

40% sodium nitrate (NaNO_3)

+

60% potassium nitrate (KNO_3)

Solar Platform
Solar Tower (Spain)
source: ABERGOMA SOLAR

SandStone Plant
Novada (USA)
source: PROTERMO SOLAR

Introducing Nanoparticles of SiO_2 in NaNO_3

Since the controversial among experimental results, we have performed the experimental calculations of C_p with nanoparticles of SiO_2 of 5-15 nm of diameter.

Thermal Capacity pure NaNO_3 (experimental vs. MD)

$$Q_{\text{sensible}} = \int_{T_1}^{T_2} C_p \cdot dT$$

Density values are also in close agreement with experimental results (3%), then validating the force field used.

$$C_p (500^\circ\text{C}) = 1.5 \text{ J g}^{-1} \text{ K}^{-1}$$

$$C_p (500^\circ\text{C}) = 1.8 \text{ J g}^{-1} \text{ K}^{-1} (\text{simulated})$$

try to visualize these mechanisms with the help of molecular dynamics simulations

Radial distribution pure NaNO_3 

- Lost of crystalline order
- melting temperature range [550-600]K
 $T_{m,exp} = 581\text{K}$

Introducing Nanoparticles of SiO_2 in NaNO_3 

1 nm of diameter in concentrations in the range 0 to 10%

Nanoparticle concentration (%)	C_p ($\phi=1\text{nm}$) $\text{J g}^{-1} \text{K}^{-1}$	C_p ($\phi=3\text{nm}$) $\text{J g}^{-1} \text{K}^{-1}$
0.2	2.62	1.90
0.5	2.60	2.25
1	2.40	2.47
2	2.45	2.10
4	1.70	---
0	1.80	---

The concentration of nanoparticles increases
nanoparticle size increases

Introducing Nanoparticles of SiO_2 in NaNO_3

773 K

Semi-solid Layer of NaNO_3 around the nanoparticle: verifying the existence of Mechanism III.

Introducing Nanoparticles of SiO_2 in NaNO_3

Comparison between experimental and simulated values.

Introducing Nanoparticles of SiO_2 in NaNO_3 

- ✓ Faujasite structures with different Al/Si ratio are more efficient for swing adsorption procedures.
- ✓ High Al content structures are optimum for TSA, medium content for VSA and low Al content for PSA.
- ✓ Concentration of nanoparticles plays a key role in the increase of thermal capacity in solar salts.
- ✓ All the molecular dynamics results obtained confirm the presence of the three mechanisms proposed.
- ✓ More studies are necessary for calculating the percentage of each mechanism in the overall effect.
